

SYNC or Swim

A Particle Model of the Interaction within Fish Schools

David Ebert and Mikaela Jordan

Tarleton State University

March 31, 2017

Synchronization

The coordination of events to operate a system in unison. Some natural physical examples:

- Circadian Rhythms
- Round of Applause (WHAT?!?! Let's try it!)

Human Swarming - Example

Coupling

One object influencing another by providing feedback. Real life examples

- Animal Swarming
- Human Imitation (Memes/Trends)

Coupled oscillators are systems of masses that are connected by springs.

Collective Behavior

• The coordinated behavior of animals of the same species and the emergent properties that arise.

Collective Behavior

- The coordinated behavior of animals of the same species and the emergent properties that arise.
- For mathematical purposes, consider a swarm as an emergent behavior with no central coordination that arises due to several simple instinctual rule that animals of a given species follow.

Collective Behavior

- The coordinated behavior of animals of the same species and the emergent properties that arise.
- For mathematical purposes, consider a swarm as an emergent behavior with no central coordination that arises due to several simple instinctual rule that animals of a given species follow.
- Other terms we will be using interchangeably with "collective behavior": swarm, school(specific to fish)

Why Do We Care?

- Learning C/CUDA
- Applying mathematical models to real life phenomenon
- How will environmental factors affect the animal aggregate
- How animal aggregates will affect the environment

As a simple model/simulation of the swarm (schooling) behavior of fish, our model represents each fish adhering to the following three rules:

As a simple model/simulation of the swarm (schooling) behavior of fish, our model represents each fish adhering to the following three rules:

Move in the same direction as your neighbors

As a simple model/simulation of the swarm (schooling) behavior of fish, our model represents each fish adhering to the following three rules:

- Move in the same direction as your neighbors
- Remain close to neighbors

As a simple model/simulation of the swarm (schooling) behavior of fish, our model represents each fish adhering to the following three rules:

- Move in the same direction as your neighbors
- Remain close to neighbors
- Avoid collisions with neighbors

The Mathematics

- Lagrangian Algorithm
 - Agent Based Model following individual particles in school
- Metric distance model calculate forces on individual particles based on distance to other particles

At every timestep, the following calculations occur for each particle (let's call it particle i):

• Calculate distance between particle *i* and every other particle.

- Calculate distance between particle *i* and every other particle.
- If the distance between some particle j and particle i is smaller than predefined search distance, then use Hook's law to determine the forces between particle j and particle i.

- Calculate distance between particle *i* and every other particle.
- If the distance between some particle j and particle i is smaller than predefined search distance, then use Hook's law to determine the forces between particle j and particle i.
- Use force calculated above to update particle i's velocity as follows:

- Calculate distance between particle *i* and every other particle.
- If the distance between some particle j and particle i is smaller than predefined search distance, then use Hook's law to determine the forces between particle j and particle i.
- Use force calculated above to update particle i's velocity as follows:

$$v_i = v_i + a_i dt$$

At every timestep, the following calculations occur for each particle (let's call it particle i):

- Calculate distance between particle *i* and every other particle.
- If the distance between some particle j and particle i is smaller than predefined search distance, then use Hook's law to determine the forces between particle j and particle i.
- Use force calculated above to update particle i's velocity as follows:

$$v_i = v_i + a_i dt$$

• And update particle i's position using:

- If the distance between some particle j and particle i is smaller than predefined search distance, then use Hook's law to determine the forces between particle j and particle i.
- Use force calculated above to update particle i's velocity as follows:

$$v_i = v_i + a_i dt$$

• And update particle i's position using:

$$p_i = p_i + v_i dt$$

Simulations

Where Do We Go From Here?

- Add initial conditions for species-specific parameters
 - Density of swarms, how they behave towards targets and obstacles, etc.
- Move calculations from CPU to GPU to speed calculation time

THANK YOU

Thank you to Dr. Wyatt and the Particle Modelling Lab for their time and resources.
